The diagram illustrates the Bubble Sort algorithm in C. It features a large blue 'C' logo on the left. In the center, two horizontal arrays of numbers are shown. The top array contains the numbers 46, 43, 52, 21, 33, 22, and 89. Below it, the text 'Bubble Sort' is written with a downward arrow pointing to a second array containing the numbers 21, 22, 33, 43, 46, 52, and 89. The background is a dark blue gradient with a teal wave pattern at the bottom. The website address 'www.educba.com' is visible in the bottom right corner.

46	43	52	21	33	22	89

## Introduction to Bubble Sort in C

In C programming language there are different sorting techniques such as selection sort, bubble sort, merge sort, quick sort, heap sort, insertion sort, etc. Sorting is a process of arranging elements or items or data in a particular order which is easily understandable to

(<https://www.educba.com/software-development/>)

## Working of Bubble Sort with an Example and Algorithm

In general, bubble sort is also known as a sinking sort where each adjacent element is checked and swap if there are not in the correct order and this swapping of elements process is continued until there are no items or elements are left for swapping. Let us see the algorithm:

## Algorithm

Let us consider a list of elements.

**Step 1:** In the first step it will start with the first element of the list and starts comparing it with the next element.

**Step 2:** This checking and swapping of the elements are done on the entire list. So to do this first element is compared with the adjacent element. That can be done using for loop

For all elements of the list

if list[ item at index 1] > list [item of index + 1]

**Step 3:** After comparing the elements swap these in ascending order using the below swap function (list[item at index 1 ], list [item of index + 1])

**Step 4:** After examining all the elements then these are swapped in ascending order.

## Example

Let us consider an example below for sorting the list 46, 43, 52, 21, 33, 22, 89 using bubble sort.

```
#include <stdio.h>

void swap_ele(int *p, int *q)
{
```

[\(https://www.educba.com/software-development/\)](https://www.educba.com/software-development/)

```
void bubble_Sort(int a[], int n)
{
    int i, j;
    for (i = 0; i < n-1; i++)
        for (j = 0; j < n-i-1; j++)
            if (a[j] > a[j+1])
                swap_ele(&a[j], &a[j+1]);
}

void print_list(int a[], int size)
{
    int i;
    for (i=0; i < size; i++)
        printf("%d ", a[i]);
    printf("\n");
}

int main()
{
    int a[] = {46, 43, 52, 21, 33, 22, 89};
    int n = sizeof(a)/sizeof(a[0]);
    bubble_Sort(a, n);
    printf("Sorted list using bubble sort: \n");

    print_list(a, n);
    return 0;
}
```

---

In the above code, we have written 3 different functions each of which work differently firstly, we have written a function for swapping the numbers “swap\_ele” is the function in which we take two variables by passing them as a parameter where one variable store the first element and the second variable stores the second element and inside the function we use “temp” variable where we use to store the value and swap the elements.

In the second function, it is a very important function which has the logic of working of bubble sort using the “swap\_ele” function. In this “bubble\_Sort” function we declare two variables “ i ” and “ j ”, where if we the value of i = 0 then the j loop points to the largest element of the list and after incrementing “i” value by 1 where i = 1, then “ j ” loop points to the second largest element of the list and so on. Then using “for” loop we can traverse the list and then using “ if ” loop we are comparing the values stored in the two variables among which element is smaller is swapped to left and the bigger value elements get swapped to the right-hand side of the list using “swap\_ele” function.

The third function is to just print the sorted list using the “for” loop and arrange in ascending order. Then lastly to compile the program we need to write the main function in which we declare a list and use the “bubble\_sort” function on that list and print the sorted list using the “print\_list” function.

So in general, the bubble sort working is very simple, where it will traverse the entire list and the largest item of the list will be swapped with all the items in the list and this largest element is placed at the extreme right of the list. So when the largest element is placed at the right

position in the list now that element is not considered while comparing now again the s largest element is compared to all the leftover elements excluding the largest element also this second largest element is also placed at the rightmost side of the list that is just before the

(<https://www.educba.com/software-development/>)

## Conclusion

Bubble sort is one of the simplest sorting techniques, which is also known as a sinking sort. This sorting technique is usually used when introducing the sorting concept. Bubble sort is a technique of sorting or arranging the items of the list or array in either ascending order or descending order. This technique first determines the largest element in the list or array and then compares it with other items and then it is placed in the extreme right of the list and this process is continued until there are no items are there to swap with.
